Two crystal caves, extremely rich in formations, became known in the southernmost part of Hungary in the last decades.

On November 12, 1984, during an explosion, a 1 m cave mouth opened in the upper level 116 of the Beremend limestone quarry, on the NE front, at the foot of the wall, which led into a hall full of debris. It is a great result, that this cave did not share the fortune of its about two dozens fellows, which were demolished on the spot. The discovery was reported to the Ministry of Environmental Protection and Nature Conservation, which immediately delegated a research team under the guidance of Katalin Takács-Bolner. They explored only the first hall of the cave and realised that there is a passage leading further. Still in this year, on December 6, there was a second field survey. In this occasion, more helping hands were invited – supposing it may be carry out demolition work. Thus, among others, I myself also took part in this survey on behalf of the Rózsadomb (Rose Hill) "Kinizsi" Speleological Society together with Péter Adamkó, when we discovered the back parts. At the beginning of 1985, the team of József Kárpát explored also the other branch of the cave, which ends in an active lake filled by 18ºC water.
